1.0 - APRESENTAÇÃO

Este relatório diz respeito ao estágio supervisionado, realizado por ÉRICA MEDEIROS C. B. DE SOUSA, sob número de matrícula 8911223 - 6, aluna do curso de ENGENHARIA CIVIL da Universidade Federal da Paraíba - Campus II, realizado no Laboratório de Hidráulica da Área de Engenharia de Recursos Hídricos, sob regime parcial de 10 horas semanais. Tendo como supervisora a Professora MÁRCIA MARIA RIOS RIBEIRO e Coordenador o Professor RICARDO CORREIA LIMA.

As atividades realizadas durante o estágio, compreenderam o período de 02/05/94 a 09/09/94, perfazendo um total de 180 horas.

2.0 - INTRODUÇÃO

O presente relatório foi dividido em duas etapas:

A primeira etapa visa a caracterização dos dados geométricos fornecidos (cota, área e volume) de alguns açudes do Estado da Paraíba. Estes dados são essenciais para o estudo da avaliação das disponibilidades hídricas superficiais das bacias hidrográficas nas quais se situam aqueles açudes.

A segunda etapa visa o estudo da disponibilidade hídrica do reservatório Epitácio Pessoa (Boqueirão), manancial localizado no município de Boqueirão e que abastece entre outras cidades, Campina Grande. O Epitácio Pessoa tem um volume máximo armazenável de aproximadamente 536 milhões de m³.

Estes dados deverão fazer parte do Plano Estadual de Recursos Hídricos, conforme consta em proposta técnica encaminhada à Secretaria de Planejamento do Estado da Paraíba - SEPLAN, pela Associação Técnica e Científica Ernesto Luis Oliveira Júnior - ATECEL (UFPB/ATECEL, 1993).

3.0 - PRIMEIRA ETAPA

3.1 - AVALIAÇÃO DAS CURVAS COTA X ÁREA E COTA X VOLUME

As curvas Cota X Área e Cota X Volume são usadas como dados essenciais para a avaliação quantitativa das disponibilidades hídricas dos reservatórios.

A partir dos dados de Cota, Área e Volume fornecidos pelos órgãos estaduais e com a ajuda do software Lotus 1-2-3 (SWENSSON e GOMES, 1986), foi possível a construção das curvas cota X área e cota X volume, curvas estas usadas como dados essenciais para a avaliação quantitativa das disponibilidades hídricas dos reservatórios.

Depois de passar todos os dados para a planilha eletrônica, faz-se necessário a correção do volume fornecido. Essa correção é feita através da seguinte expressão:

$$\text{VOL CORR} = \left\{ \frac{(A1+A2)}{2} \cdot (C2 - C1) \right\} + \text{vol anterior}$$

onde:

VOL CORR - volume corrigido

A1 - Área do espelho correspondente a cota anterior.

- A2 - Área do espelho correspondente a cota posterior.
- C1 - Cota anterior.
- C2 - Cota posterior.

Em seguida, observa-se a diferença entre o volume original fornecido pelas tabelas e o volume "teórico" esperado ou volume corrigido (dado pela expressão anterior).

Para que se tenha dados coerentes das características geométricas do açude, faz-se necessário que a diferença entre o volume "teórico" esperado e o volume apresentado pelas tabelas seja aproximadamente zero.

A tabela a seguir ilustra a maneira como é feita a correção do volume para o Açude Barra de Xandu:

Tabela 1 - dados de cota, área e volume para o Açude Barra do Xandu.

| Cota (m) | Área ² (m) | Volume ³ (m) | Vol.corr. ³ (m) | Dif. ³ (m) |
|-------------|------------------------------|--------------------------------|-----------------------------------|------------------------------|
| 11 | 400 | 0 | 0 | 0 |
| 12 | 1200 | 800 | 800 | 0 |
| 13 | 14800 | 8800 | 8800 | 0 |
| 14 | 42400 | 97400 | 97400 | 0 |
| 15 | 93000 | 105100 | 105100 | 0 |
| 16 | 144400 | 223800 | 223800 | 0 |
| 17 | 196800 | 394400 | 394400 | 0 |
| 18 | 267200 | 626400 | 626400 | 0 |
| 19 | 336000 | 928000 | 928000 | 0 |

Foram fornecidos dados de 83 (oitenta e tres) açudes (Anexo 1). Dentre os dados fornecidos, apenas 36 (trinta e seis) açudes obtiveram a "diferença" zero referenciada anteriormente, os demais foram excluídos, pois apresentavam irregularidades, tais como: dados ilegíveis; dados incompletos (Açudes Caraiqueira, Macapã, Namorado, Ouro Velho, Tauá). No anexo 2 são mostradas as tabelas dos 36 açudes que tiveram seus dados inconsistentes.

No Anexo 3 estão as figuras correspondentes aos erros acima citados.

O reconhecimento dos açudes foi feito e georeferenciado pelas coordenadas (cartesianas e geográficas) do centro de massa dos mesmos a partir da observação em mapas na escala 1:100.000, restituídos pelo LRMS - Pb (Laboratório de Meteorologia, Recursos Hídricos e Sensoriamento Remoto da Paraíba), com imagens LANDSAT de 1989 e 1990 e cedidas pelo SAIA (Secretaria de Agricultura, Irrigação e Abastecimento do Estado da Paraíba).

O levantamento foi executado no sentido oeste-leste, atribuindo-se uma numeração crescente como critério de indentificação e contagem dos açudes, tendo-se medido as áreas dos espelhos d'água. No total foram cadastrados 4.898 açudes em todo o Estado da Paraíba. Para açudes de maior porte foram planimetrados também as áreas das bacias hidrográficas.

Dos 83 açudes analisados, apenas 16 foram localizados no mapa referenciado acima, os demais estão enumerados na Tabela 2, mostrada abaixo:

Tabela 2 - Açudes Plotados no Mapa com escala 1:100.000

| Açude | Município | Volume máximo (m ³) |
|-------------------|----------------------|---------------------------------|
| Alto Branco | Nova Palmeira | 64.546 |
| Brejinho | Juarez Távora | 789.000 |
| Cachoeira da vaca | Cachoeira dos Índios | 339.156 |
| Catolé | Manaira | 8.655.800 |

cont. do da Tabela 2

| Gurjão | Gurjão | 1.929.250 |
| Limeirão | S. José de Pira- nhas | 3.051.125 |
| Nazaré | Itaporanga | 5.499.186 |
| Novo | Tavares | 706.080 |
| Olivedos | Olivedos | 5.875.124 |
| Zé Francisco | Bonito de Sta. Fé | 584.080 |

3.2 - CONCLUSÃO

Apenas 36 açudes analisados apresentaram dados confiáveis, ou seja, dados cuja diferença entre o volume "teórico" e o volume fornecido pelas tabelas foi de aproximadamente zero, o que nos serve de subsídio para a obtenção das curvas cota X área e cota X volume dos mesmos.

Quanto aos outros açudes, nos quais apresentaram dados inconsistentes, é prudente que se realize uma batimetria, para que se tenha os dados geométricos reais dos açudes, para posterior estudo da disponibilidade hídrica.

4.0 - SEGUNDA ETAPA

4.1 - INTRODUÇÃO

A segunda etapa deste relatório visa o estudo da disponibilidade hídrica do Açude Epitácio Pessoa(Boqueirão), açude este que abastece dentre outros municípios, a cidade de Campina Grande.

Para tal estudo, foi usada a simulação do balanço hídrico do Epitácio Pessoa, auxiliado pelo programa HEC-3 (Ribeiro, 1990), que nos fornece dados para a obtenção da curva de garantia mensal ou curva de permânencia.

4.2 - AVALIAÇÃO DA DISPONIBILIDADE ATUAL DO AÇUDE EPITÁCIO PESSOA

A avaliação da disponibilidade hídrica do Açude Epitácio Pessoa se faz mediante a metodologia de simulação do balanço hídrico no referido açude.

O programa HEC-3 fornece dados importantes para a simulação da operação de um reservatório. Neste relatório em particular, foram usados apenas os dados necessários para que se fizesse o estudo da disponibilidade hídrica do Açude Epitácio Pessoa.

Para executar o algoritmo HEC-3 é preciso que se disponha de dois arquivos de trabalho: o arquivo de entrada e o arquivo de saída.

O arquivo de entrada é composto de dados tanto geométricos (cota área e volume), quanto hidrológicos (vazão e evaporação mensais). No nosso estudo trabalhou-se com dados de vazão afluente para o período de 21 anos (de 1963, inclusive até 1983).

O volume inicial, para Janeiro de 1963 (início do estudo), foi tomado como sendo 10% do volume máximo armazenado, ou seja $53.600.000 \text{ m}^3$.

O volume inativo ou volume "morto", também foi considerado como 10% do valor máximo armazenável.

No arquivo de entrada do Epitácio Pessoa (Anexo 4), os dados geométricos e os hidrológicos são encontrados sob a forma de variáveis. Abaixo estão listados as variáveis usados no estudo do Epitácio Pessoa:

RE - valor da cota

RS - valor do volume armazenável

RA - valor da área do espelho do Epitácio Pessoa

IN - vazão afluente + precipitação

YE - evaporação

QR - vazão de demanda ou regularizável

O arquivo de saída é o resultado da simulação do balanço hídrico, realizado pelo HEC-3, que fornece os dados essenciais para o estudo da disponibilidade hídrica do manancial referido.

A dinâmica do processo do balanço Hídrico mensal pode ser sintetizada através da seguinte expressão:

$$V_i = V_{i-1} + V_{ci} + V_{pi} - V_{ei} - V_{qi}$$

onde:

V_{i-1} - Volume de água armazenado no reservatório no final do mês $i-1$;

V_i - Volume de água armazenado no reservatório no final do mês i ;

V_{ci} - Volume de água afluente ao reservatório

decorrente do escoamento superficial da bacia de contribuição, durante o mês i ;

VE_i - Volume de água retirado do reservatório decorrente das perdas por evaporação na bacia hidráulica;

VQ_i - Volume de água retirado do reservatório para suprir as possíveis demandas hídricas, durante o mês i .

Para o estudo do Açude Epitácio Pessoa, foram somado as contribuições de volume de água decorrente do escoamento superficial e o da precipitação.

Dentre os vários dados fornecidos, destaca-se aquele que é de maior importância: o número de meses em que a vazão regularizável assumida, não atendeu a demanda, ou seja, o número de meses em que houve falhas.

Sabendo-se o número de meses em que houve falhas(n), é possível conhecer a porcentagem de ocorrência de falhas durante o período de simulação ($m = 21$ anos), pela seguinte expressão:

$$F = (n/m) \cdot 100$$

Dai resulta o valor do nível de atendimento do manancial, ou seja $G = 100 - F$.

De posse da vazão regularizável e do nível de atendimento é possível a construção da curva de garantia mensal do Açude Epitácio Pessoa (Boqueirão).

A tabela 3 ilustra as vazões regularizáveis assumidas, com seus respectivos valores de ocorrência de falhas e nível de figura 1 mostra a curva de Garantia Mensal para o açude Epitácio Pessoa.

Tabela 3 - Vazões regularizáveis utilizadas na simulação do balanço hídrico no açude Epitácio Pessoa.

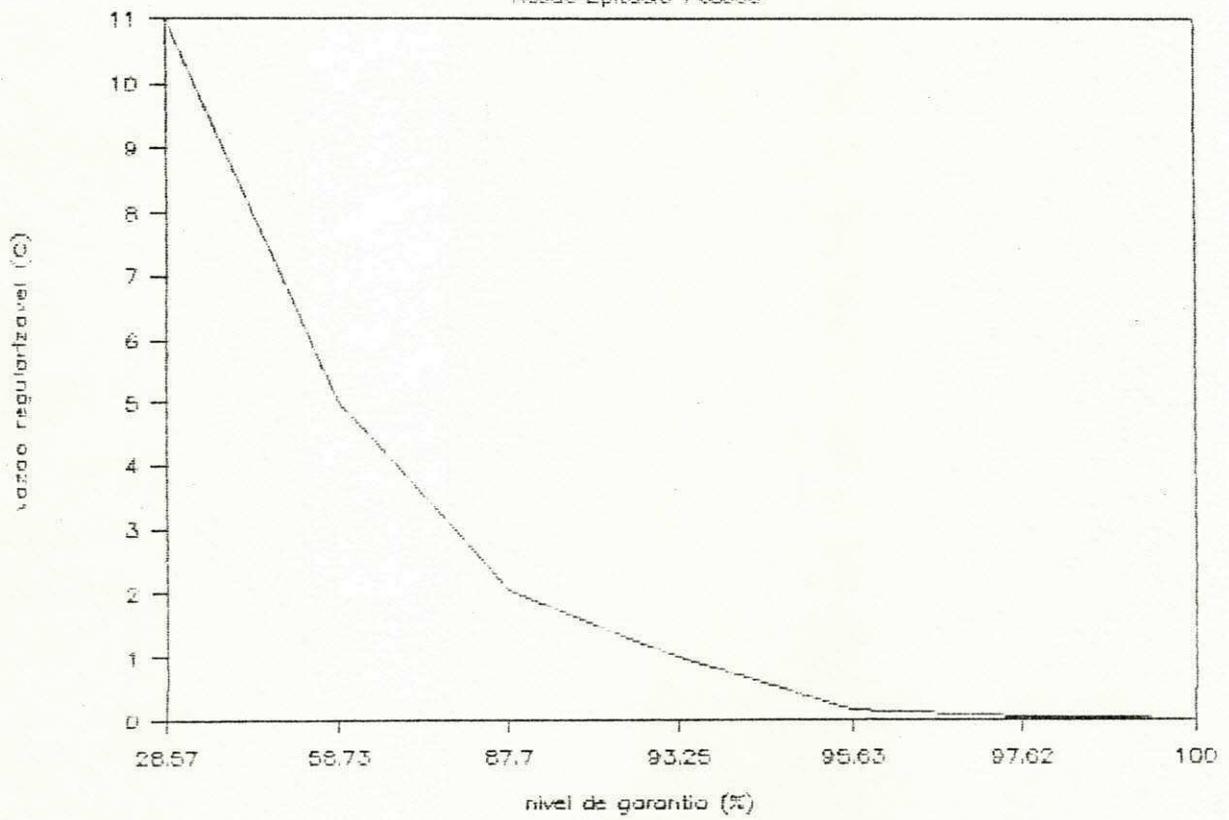

| Q (Vazão) $\frac{m^3}{s}$ | F (Frequência de falhas) $F = \frac{(n/m) \cdot 100}{\%}$ | G (garantia) $G = 100 - F$ $\%$ |

CURVA DE GARANTIA MENSAL

Acude Epitacio Pessoa

4.3 - ANÁLISE DA VAZÃO REGULARIZÁVEL DO ACUDE EPITÁCIO PESSOA PARA O NÍVEL DE 90%.

A Tabela 3 fornece os dados necessários para a construção da Curva de Garantia Mensal do Açude Epitácio Pessoa .

De acordo com a Curva de Garantia, podemos analisar o açude mediante sua capacidade de atendimento. Quando o Epitácio Pessoa assume uma vazão regularizável de $2 \text{ m}^3/\text{s}$, o mesmo atende à esta vazão durante 227 meses dos 252 meses simulados, ficando o restante dos meses (25 meses) sem abastecimento.

Pode-se verificar na Curva de Garantia Mensal do açude Epitácio Pessoa, que a medida em que as vazões regularizáveis vão aumentando , a capacidade de atendimento do manancial vai diminuindo.

Analisando o arquivo de saída (Anexo 4), para uma vazão de regularização de $2.00 \text{ m}^3/\text{s}$ têm-se:

No primeiro ano simulado (1963), o Epitácio Pessoa atendeu vazões abaixo da vazão de demanda, de janeiro a abril, enquanto que de maio a dezembro ele não havia atendido a nenhuma vazão, o que indica que o ano de 1963 é um dos anos em que houve falhas no atendimento, mensuradas no programa HEC-3.

No quarto ano simulado (1966), o Açude Epitácio Pessoa atendeu perfeitamente a vazão de demanda; apre-

sentou uma escassez zero, ou seja, neste ano o manancial Epitácio Pessoa apresentou a vazão de atendimento igual a vazão de demanda.

4.3 - CONCLUSÃO

Depois da simulação de vazões concluídas, obteve-se a Curva de Garantia mensal, que servirá como dado para a avaliação e determinação da vazão aproveitável num determinado nível de risco pré - estabelecido.

Observa-se que para uma vazão de 2.00 m³/s, o açude Epitácio Pessoa garante o atendimento em 90% do tempo.

Esses dados são importantes quando se necessita saber, se um determinado manancial têm condições de abastecer a uma população durante um determinado espaço de tempo.
